

# Actuarial Decision-Support Prototype

---

A complete start-to-finish implementation report for the high-cost Medicare beneficiary risk

# 1. What Was Built

---

End-to-end system

## 2. Source Data Inventory

CMS DE-SynPUF source files are staged and standardized before aggregation to beneficiary-year gold features.

| Entity                   | Logical source       | Rows      | Silver table             |
|--------------------------|----------------------|-----------|--------------------------|
| beneficiary_summary      | beneficiary_2008     | 116,352   | silver_beneficiaries     |
| beneficiary_summary      | beneficiary_2009     | 114,538   | silver_beneficiaries     |
| beneficiary_summary      | beneficiary_2010     | 112,754   | silver_beneficiaries     |
| inpatient_claims         | inpatient_2008_2010  | 66,773    | silver_inpatient_claims  |
| outpatient_claims        | outpatient_2008_2010 | 790,790   | silver_outpatient_claims |
| carrier_claims           | carrier_2008_2010_a  | 2,370,667 | silver_carrier_claims    |
| carrier_claims           | carrier_2008_2010_b  | 2,370,668 | silver_carrier_claims    |
| prescription_drug_events | pde_2008_2010        | 5,552,421 | silver_pde               |

### 3. Data Pipeline and Gold Grain

---

Medallion architecture

## 4. Chronic Burden Signal

Median annual claim cost rises with chronic-condition count, supporting chronic burden features and nonlinear terms.

## 5. Target Balance by Year

The top-decile target creates an intentionally imbalanced but operationally meaningful high-cost label.

## 6. Feature Signal Checks

Utilization intensity, provider count, chronic burden, and cost features show the strongest prospective signal.

## 7. Prospective Target and Leakage Controls

---

Features are measured in beneficiary-year  $t$ . The high-cost label is computed from annual claim

# 8. Final Held-Out Test Results

Gradient boosting is selected for operational ranking because it has the strongest held-out PR-AUC and top-k capture profile.

| Model               | Accuracy | Precision | Recall | ROC-AUC | PR-AUC | Top 5% Capture | Top 10% Capture | Top 10% Lift |
|---------------------|----------|-----------|--------|---------|--------|----------------|-----------------|--------------|
| Logistic Regression | 0.8603   | 0.3432    | 0.4469 | 0.8060  | 0.3634 | 0.2386         | 0.3799          | 3.7994       |
| Gradient Boosting   | 0.8533   | 0.3329    | 0.4769 | 0.8099  | 0.3879 | 0.2511         | 0.3877          | 3.8767       |
| Random Forest       | 0.8525   | 0.3207    | 0.4747 | 0.8030  | 0.3634 | 0.2493         | 0.3819          | 3.8192       |
| XGBoost             | 0.7131   | 0.2179    | 0.7145 | 0.7989  | 0.3617 | 0.2322         | 0.3691          | 3.6897       |

## 9. Top-K Capture Curve

Top-k capture shows how many true high-cost beneficiaries are captured when operations can only review the highest-risk fraction.

## 10. Top-K Lift Curve

Lift translates ranking quality into operational concentration versus random selection.

## 11. Model Selection Interpretation

---

- Logistic regression remains the interpretable statistical baseline.

## 12. API and Serving Layer

---

**FastAPI endpoints**

## 13. Streamlit Frontend and Demo

---

The frontend runs from `frontend/app.py` through `./run_frontend.sh` and is available at

## 14. Simulated MDP/Q-Learning Policy Layer

---

The policy layer maps supervised risk into an operational MDP state.

## 15. Governance and Methodological Controls

---

- Intended use: care-management queue prioritization, actuarial risk segmentation, and

## 16. Verification Completed

---

The final local verification sequence was run after submission-control edits.

## 17. How to Reproduce

---

**Local development**

## 18. Final Takeaway

---

The project is a governed actuarial risk-ranking and decision-support pipeline.
